PLANNING

A SOLUBILITY INVESTIGATION

hypothesis/objective

To investigate how temperature affects the amount of salt that will dissolve in water

MATERIALS

gauze, measuring cylinder, thermometer, beaker, spatula, tripod, bunsen burner, salt

STEPS/PROCEDURE

put 75cm^3 in a beaker

then measure the temperature with a thermometer record it

pour salt into the water until you reach a saturated solution record it

put the beaker on top of a wired gauze supported by a tripod stand

put bunsen burner under the tripod and heat the solution

put thermometer in water and extinguish the flame at 40 degree celcius

pour salt until saturated solution

further heat it until 60 degree celcius and repeat by adding salt until saturated before further heating until 80 degree celcius pour salt until saturated solution

measure all of this and record it preferably using a table

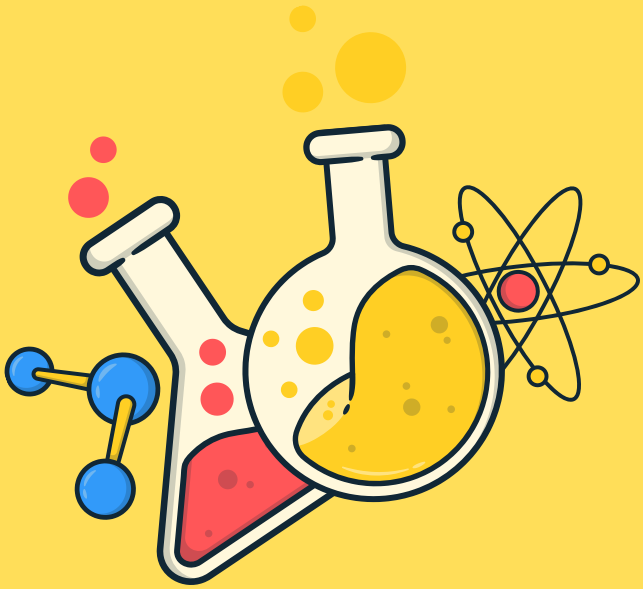

TABLE CHART

temp of water	No of spatulas with salt
29°c	7
40°c	10
60°	12
80°c	13

LINE DIAGRAM

RESULT

The result shows how the number of spatula increase when the temperature increase

at the base tempereature 29°c we got 7 spatulas and at 40° degree celcius we got 10 and so on until 80° celcius where we got 13 spatulas filled with salt

CONCLUSION

The conclusion is that when we heat up the solvent(water) the molecule spread out making more space for the solute(salt) therefore increasing the saturation of the solution

VARIABLES

independent variables:Temperature

dependent variable:the spatulas of salt used

control variable:the type of salt and amount of water
